Sergio Schvezov: Fingerprint Reader Support for Lenovo x390Y on Ubuntu [2]

How to get a direct WebRTC connections between two computers [3]

WebRTC is a standard real-time communication protocol built directly into modern web browsers. It enables the creation of video conferencing services which do not require participants to download additional software. Many services make use of it and it almost always works out of the box.

The reason it just works is that it uses a protocol called ICE to establish a connection regardless of the network environment. What that means however is that in some cases, your video/audio connection will need to be relayed (using end-to-end encryption) to the other person via third-party TURN server. In addition to adding extra network latency to your call that relay server might overloaded at some point and drop or delay packets coming through.

Here's how to tell whether or not your WebRTC calls are being relayed, and how to ensure you get a direct connection to the other host.
