The FreeBSD project is in the process of switching its version-control system to git. Having passed through RCS, CVS and SVN, the project is now ending up with the same tools as (most) everyone else.

FreeBSD has three main repositories: src (the source code of the operating system itself and its supporting tools and the whole base userland), doc (all the documentation, handbooks, guides, etc) and ports (the descriptions of how to build third-party software like KDE Frameworks).
