The week prior put together frequent Tumbleweed snapshots and the rolling release has been delivering continuous daily software updates since Oct. 27.

Updated documentation for the --whitespace-off feature in urlscan 0.9.7 was made in the latest 20211102 snapshot. Two other packages were also included in the snapshot; both packages were 2.0.99.2 versions of the Chinese input method ibus-sunpinyin and sunpinyin 2.0.99.2.

Snapshot 20211101 updated two packages. The general-purpose parser bison updated to version 3.8.2. It removed support for the YYPRINT macro and added a new C++ native GLR parser. The other package to update in the snapshot was gdb 11.1; the debugger added many maintenance scripts and removed several obsolete Fedora patches. The gdb package now supports general memory tagging functionality if the underlying architecture supports the proper primitives and hooks, which is currently only enabled for the AArch64 Memory Tagging Extension.
