My conclusion is damning with faint praise: at least it wasn't any worse. And with these tweaks it works fine. If you're on F34 you have no reason not to upgrade, and if you're on F33 you won't have much longer until you have to (and you might as well just jump right to F35 at that point). But it's still carrying an odd number of regressions (even though, or perhaps despite the fact, the workarounds for F35 are the same as F34) and the installation on the T2 was bumpier than the Blackbird for reasons that remain unclear to me. If you run KDE or Xfce or anything other than GNOME, you shouldn't have any problems, but if you still use GNOME as your desktop environment you should be prepared to do more preparatory work to get it off the ground. I have higher hopes for F36 because we may finally get that float128 update that still wrecks a small but notable selection of packages like MAME, but I also hope that some of these regressions get dealt with as well because that would make these updates a bit more liveable. Any system upgrade of any OS will make you wonder what's going to break this time, but the most recent Fedora updates have come off as more fraught with peril than they ought to be.
