As I'm fairly sure you know, Linux is known to be capable of virtually running everywhere and doing anything. Not only does it run on a majority of our world's supercomputers, but it can also run on the tiniest systems ever made, just as the size of a quarter. Today we'll be taking a look at a distribution of Linux that is famous for being able to run with very little hardware requirements, Puppy Linux.

Puppy Linux isn't based on another distribution; it is developed completely on its own. The system can, however, be built from packages of other distributions like Ubuntu, Arch Linux, and Slackware thanks to the Woof project. One of the great advantages of this distribution is its very small size. Generic Puppy Linux offers a 128MB ISO to download, with both "new" and long-term release options available. The small size lets Puppy Linux boot on any CD or USB stick and run with a weak CPU and low amount of memory.
