Security researchers have discovered what appears to be an experimental Linux rootkit designed to infect its highly select victims during a classic drive-by website attack.

Posted anonymously to Full Disclosure on 13 November by an annoyed website owner, the rootkit has since been confirmed by CrowdStrike and Kaspersky Lab as being distributed to would-be victims via an unusual form of iFrame injection attack.

Aimed specifically at users of the latest 64-bit Debian Squeeze kernel (2.6.32-5), the rootkit has been dubbed ?Rootkit.Linux.Snakso.a? by Kaspersky Lab.
