LibreSSL is a fork of the SSL/TLS protocol code from OpenSSL and aims to rewrite code as well as remove a lot of functionality that is only of limited use or has been deprecated and destined for removal. Developers will still worry about portability and they will work on multi-OS support once LibreSSL has an established baseline. For now, OpenBSD is the only supported platform of LibreSSL and there's already plans to ship it as part of OpenBSD 5.6.
